Nodes in an ad hoc wireless network share a common broadcast radio channel. Since the radio spectrum is limited, the bandwidth available for communication in such networks is also limited. Access to this shared medium should be controlled in such a manner that all nodes receive a fair share of the available bandwidth, and that the bandwidth is utilized efficiently.

Wireless ad hoc networks can take the form of a mesh networks or others. A wireless ad hoc network does not have fixed topology, and its connectivity among nodes is totally dependent on the behavior of the devices, their mobility patterns, distance with each other, etc. Hence, wireless mesh networks are a particular type of wireless ad hoc networks, with special emphasis on the resultant network topology.

Wireless ad hoc network - Wikipedia

There are two architectures available, namely standalone and centrally coordinated wireless network. Standalone architecture (Ad hoc mode) By using ad hoc mode, all devices in the wireless network are directly communicating with each other in peer to peer communication mode. No access point (routers/switches) is required for communication between devices.

Various wireless communication networks have been developed, such as cellular networks [2], wireless LANs (WLAN) [3], Bluetooth networks], Ultra-wideband (UWB) networks , Mobile Ad Hoc Networks (MANETs, and WiMax . Among these, cellular networks, Bluetooth networks, and WLANs are the most widely used.

Ad-Hoc Networks consist of peer-to-peer communicating nodes that are highly mobile. As such, an ad-hoc network lacks infrastructure and topology of the network changes dynamically. The task of routing data from a source to a destination in such a network is challenging. Several routing protocols have been proposed for wireless ad-hoc networks.
